

Vector Cross Product

Basics

- First, the cross product $\mathbf{A} \times \mathbf{B}$ is a new vector that is perpendicular to both \mathbf{A} and \mathbf{B} .
- Given the two vectors $\mathbf{A} = \langle a_1, a_2, a_3 \rangle$ and $\mathbf{B} = \langle b_1, b_2, b_3 \rangle$, the cross product $\mathbf{A} \times \mathbf{B} = \langle a_2 \cdot b_3 - a_3 \cdot b_2, a_3 \cdot b_1 - a_1 \cdot b_3, a_1 \cdot b_2 - a_2 \cdot b_1 \rangle$.
- You can determine the cross product by the following approach which is used to compute the **determinant of the matrix**.

First, set up a matrix with the first row = $\mathbf{i} \ \mathbf{j} \ \mathbf{k}$, the second row = vector \mathbf{A} , and the third row = vector \mathbf{B} . Then, duplicate the same three rows to the right.

Get the positive terms by drawing diagonal lines from the the $\mathbf{i}, \mathbf{j},$ and \mathbf{k} entries on the left. Multiply the entries to get $(a_2 \cdot b_3)\mathbf{i} + (a_3 \cdot b_1)\mathbf{j} + (a_1 \cdot b_2)\mathbf{k}$.

Now, get the negative terms by drawing diagonal lines from the $\mathbf{i}, \mathbf{j}, \mathbf{k}$ entries on the right. Multiply the resultant entries to get $-(a_3 \cdot b_2)\mathbf{i} - (a_1 \cdot b_3)\mathbf{j} - (a_2 \cdot b_1)\mathbf{k}$.

So, put it all together and you get $\mathbf{A} \times \mathbf{B} = (a_2 \cdot b_3 - a_3 \cdot b_2)\mathbf{i} + (a_3 \cdot b_1 - a_1 \cdot b_3)\mathbf{j} + (a_1 \cdot b_2 - a_2 \cdot b_1)\mathbf{k}$

- Note that the cross product $\mathbf{A} \times \mathbf{B}$ is defined = $\mathbf{n} | \mathbf{A} | \cdot | \mathbf{B} | \sin \theta$, where \mathbf{n} is the unit vector perpendicular to both \mathbf{A} and \mathbf{B} and θ is the angle between \mathbf{A} and \mathbf{B} .
- If \mathbf{A} and \mathbf{B} are different vectors then the magnitude of $\mathbf{A} \times \mathbf{B} = | \mathbf{A} \times \mathbf{B} | = | \mathbf{A} | \cdot | \mathbf{B} | \sin \theta$ = the **area of the parallelogram** formed by the two vectors \mathbf{A} and \mathbf{B} .
- Note that if you have any vector \mathbf{C} that is not in the same plane as \mathbf{A} and \mathbf{B} , then the three vectors form a **parallel-piped** (a box that is tilted at an angle Φ , the angle between \mathbf{C} and $\mathbf{A} \times \mathbf{B}$). The **volume of the parallel-piped** = $(\mathbf{A} \times \mathbf{B}) \cdot \mathbf{C}$, which is the dot product of $(\mathbf{A} \times \mathbf{B})$ with \mathbf{C} . See the picture below. Note the parallelogram base formed by \mathbf{A} and \mathbf{B} .

\mathbf{A} and \mathbf{B} are in the plane. \mathbf{C} is above the plane.
